Dual drug therapy best for delaying BPH progression

December 18, 2003

By Anthony J. Brown, MD

NEW YORK (Reuters Health) - Combination therapy with doxazosin and finasteride delays the progression of benign prostatic hyperplasia (BPH) to a greater extent than treatment with either drug alone, according to study findings published in the December 18th issue of The New England Journal of Medicine.

"I think it is an important study because it is ... very well done and it involves longer follow-up than most other studies," Dr. E. Darracott Vaughan, Jr., author of a related editorial, told Reuters Health.

"The follow-up period is particularly important because an earlier study of just 1 year's duration failed to show a benefit for dual drug therapy," noted Dr. Vaughan, from Weill Medical College of Cornell University in New York. "The current study verified this, but went on to show that a benefit emerged later."

In the new study, Dr. Claus G. Roehrborn, from the University of Texas Southwestern Medical Center in Dallas, and colleagues assessed the outcomes of 3,047 men with BPH who were

Scoliosis
Story List
The use of the Rosenberger brace is not effective in the treatment of progressive adolescent idiopathic scoliosis, according to a study published in the July 1, 2004, issue of Spine.
Dr. Mark J. Spoonamore from the University of Southern California and colleagues conducted a retrospective chart review to evaluate the efficacy of the Rosenberger thoracic lumbar sacral orthosis in preventing curve progression in adolescent idiopathic scoliosis.
Seventy-one patients aged 9 to 16 years with progressive adolescent idiopathic scoliosis treated with the Rosenberger brace were evaluated an average of 2.3 years after brace discontinuation. Initial curves averaged 29 degrees. Braces were prescribed for 16 to 20 h/d and worn for an average of 3.2 years. All patients were skeletally immature at the time of bracing.
The researchers found that 21 patients (30%) underwent instrumentation and arthrodesis despite bracing. Forty patients (56%) had more than 5 degrees of progression. Overall, 43 patients (61%) had surgery and/or progressed by the time of follow-up. The average curve correction was 33% in patients who did not have surgery and 21% in those patients who did. Other significant factors associated with brace failure included absence of menarche before treatment, younger age at presentation and initial bracing, increased apical rotation of the primary curve at presentation, and a thoracic curve pattern.
The researchers conclude that the Rosenberger brace demonstrated an overall failure rate similar to untreated rates from published natural history studies, though subgroups of patients had lower failure rates. They note that these findings suggest the need for further refinement of the indications for the Rosenberger brace.
In other news, the effect of bracing on the quality of life (QOL) of adolescents with idiopathic scoliosis was examined in a study published in the May/June 2004 issue of The Spine Journal.

Ear Infections
What causes an ear infection?
A tube called the eustachian (say: "you-stay-shun") tube connects the middle ear with the back of the nose. Normally this tube lets fluid drain out of the middle ear. If bacteria or viruses infect the lining of your child's eustachian tube, the tube gets swollen and fills with thick mucus. This keeps fluid in the ear from draining normally. Bacteria can grow in the fluid, increasing pressure behind the eardrum and causing pain. This is called an acute ear infection, or acute otitis media.
What are symptoms of an acute ear infection?
The most common symptoms of an acute ear infection are ear pain and fever. If your child is too young to tell you what hurts, he or she may cry or pull on his or her ear. Your child may also be irritable, have trouble hearing, or not feel like eating or sleeping.
How is an acute ear infection treated?
Children may be at higher risk for ear infections if they:
Are around people who smoke.
Have had previous ear infections.
Have a family history of ear infections.
Attend day care (because they are exposed to more germs and viruses).
Were born prematurely or with a low birth weight.
Have frequent colds or other infections.
Take a bottle to bed.
Use a pacifier.
Are male (boys tend to get more ear infections than girls).

Otitis Media With Effusion
What is otitis media with effusion?
Otitis media with effusion means that there is fluid in the middle (inner) ear and that the inner ear is inflamed (swollen). (Effusion is another word for fluid.) This fluid usually doesn't bother children. It almost always goes away on its own. So, this kind of ear problem doesn't have to be treated with antibiotics, unless the fluid doesn't go away.
What causes otitis media with effusion?
Fluid may build up in the middle ear for 2 reasons. First, when a child has a cold, the middle ear
